NORTH CAROLINA COUNTIES AND DEPARTMENT OF HUMAN RESOURCES REGIONS

I. INTRODUCTION

The Public Health Statistics Branch recently produced a major publication describing North Carolina's mortality experience for the period 1971-73. *Leading Causes of Mortality - North Carolina Vital Statistics 1971-73, Volume 2* includes mapped and tabular data and associated analyses for leading causes of death in the State's 100 counties. That publication will be repeated every three years and in the interim, supportive reports of the tabular data will be published annually. This is the first of three supportive reports which may be used in conjunction with the previous major publication for purposes of current health planning and analysis. The Public Health Statistics Branch will also continue to publish the report *Detailed Mortality Statistics* which provides annual counts of deaths classified according to the specific causes of death and the age, race and sex of the decedents.

The tables of this report provide selected mortality statistics for counties, four regions and the State (see map on opposite page). Altogether, the selected causes of death accounted for 85 percent of all North Carolina deaths during 1974. Table 1 on page 9 describes the cause of death categories in terms of codes from the *International Classification of Diseases, Adapted*.

II. MORTALITY TRENDS SINCE 1960

Following an increase of 4.8 percent between 1960 and 1971, the North Carolina death rate increased an additional 4.6 percent between 1971 and 1972 to a level of 9.1 deaths per 1,000 population. Remaining unchanged in 1973, this was the highest State rate recorded since 1938.

Even more sharply than it rose during 1972, however, the rate dropped in 1974 to a level of 8.6, the lowest observed since 1967. This decrease largely involved reductions in the rates for heart disease, particularly acute myocardial infarction; cerebrovascular disease (stroke); and accidents, particularly motor vehicle accidents. Altogether, rate decreases for these causes of death accounted for about 80 percent of the overall 5.5 percent annual decline. During the sixties and early seventies, the rates for myocardial infarction and stroke had been relatively stable while the rate for motor vehicle accidents had risen.

Rates for several other leading causes of death also decreased in 1974, but the diabetes rate rose by 10 percent and rates for hypertension as well as nephritis and nephrosis remained unchanged. The 1974 rate for cancer (all sites) also reflected negligible improvement over the 1973 rate.

Altogether, then, the State's death rate has increased less than four percent since 1960, and a preponderance of this increase reflects an increasing "risk of death" due to North Carolina's changing age structure, viz., increasingly more people at older high-risk ages and fewer at young low-risk ages. Only for young people ages 15-24 has an age-specific rate increased

overall. The rate for this age group increased 4 percent, from 122.5 per 100,000 population in 1960 to 127.8 in 1974.

Race differentials in North Carolina's mortality remained high in 1974, but the gap has narrowed. While the white death rate increased six percent, from 7.7 per 1,000 population in 1960 to 8.2 in 1974, the nonwhite rate decreased three percent, from 10.2 to 9.9. On the other hand, sex differentials remained high and reductions in excessive male mortality have not occurred. Between 1960 and 1974, the male death rate rose from 9.8 to 10.1 while the female death rate increased from 6.9 to 7.2. The 1974 death rates for race-sex groups were 9.9 for white males, 7.0 for white females, 12.3 for nonwhite males and 8.5 for nonwhite females. These rates reflect reductions of 5 to 8 percent between 1973 and 1974 with each of the race-sex groups experiencing reductions in most age-specific rates. Exceptions were white females ages 20-24 and nonwhite females between the ages of 15 and 24 whose rates increased during 1974.

The most significant changes in North Carolina's mortality since 1960 involve the underlying causes of death. While rates for infant mortality as well as several other leading causes of mortality have been reduced, these improvements have been counterbalanced by deteriorating conditions with respect to other causes. In particular, the death rate for lung cancer has quadrupled; the rate for emphysema has nearly tripled and the rate for cirrhosis of the liver has more than doubled. Rates for external causes of mortality have also risen appreciably--homicide by 57 percent and suicide by 40 percent. Between 1960 and 1973, the rate for accidents likewise increased appreciably, but improvements during 1974 resulted in a net rate increase of only 11 percent since 1960.

With respect to North Carolinians ages 15-24, the rate increase of 4 percent largely reflects increases in external causes of death. It is particularly noted that this age group's rate for suicide has risen 124 percent and its rate for homicide is up 85 percent from 1960 levels. Again, the death rate for accidents has also risen, but the motor vehicle death rate for this age group was reduced substantially (18%) between 1973 and 1974.

III. MORTALITY RATES

Computation

In this report, general mortality rates are expressed as deaths per 1,000 population while all cause-specific mortality rates are expressed as deaths per 100,000 population. The infant mortality rates of Table 28 are computed as the number of infant deaths per 1,000 live births.

The following definitions apply to the rates of Tables 1-27:

Death Rate 1974: the annual death rate computed as resident deaths per 1,000 or 100,000 population. These rates permit the user knowledge of an area's status with respect to the actual incidence of mortality during 1974.

Death Rate 1972-74: the 1972-74 average annual death rate computed as average resident deaths per 1,000 or 100,000 average population. These rates permit the user knowledge of an area's status with respect to the actual incidence of mortality during the 3-year period.

Adjusted Death Rate 1972-74: the 1972-74 average annual age-race-sex-adjusted rates, computed by the direct method. Also expressed as deaths per 1,000 or 100,000 population, these rates are those which would be expected if the average annual age, race and sex composition of each county's population were the same as that estimated for the State. These rates are free of the effects of age, race and sex and thus permit the user knowledge of an area's status with respect to other determinants of mortality during the 3-year period.

Population bases for the rates described above were provided by the Office of State Planning of the North Carolina Department of Administration.

Interpretation

To assess an area's relative mortality conditions during 1972-74, both the actual rate and the adjusted rate can be compared to the State rate for a particular cause of death. Then, provided the area's actual rate represents a relatively stable situation, viz., the rate has not fluctuated widely in recent years, the following alternative diagnoses will apply:

<u>Relative Status of</u> <u>Actual Rate Adjusted Rate</u>		<u>Diagnosis</u>
Low	Low	Low mortality is not due to age, race and sex factors; other mortality conditions are favorable.
Low	High	Low mortality is due to favorable age, race and sex factors; other mortality conditions are unfavorable.
High	Low	High mortality is due to unfavorable age, race and sex factors; other mortality conditions are favorable.
High	High	High mortality is not due to age, race and sex factors; other mortality conditions are unfavorable.

Again, in assessing its relative mortality conditions, a county should be particularly aware of small numbers of deaths. In such cases, random fluctuation in the rate may render rate comparisons invalid.
